Abstract

The introduction of target-specific adult mosquito traps (Biogents® (BG) sentinel mosquito traps) in 2009/10 to detect exotic dengue vectors at Darwin port facilities has apparently increased the ability and frequency of their detection. The latest detection of Aedes aegypti at Frances Bay in Darwin in January 2011 was followed by subsequent successful elimination measures and heightened surveillance responses, which indicated no further presence of adults or larvae of this species.

Key words: Aedes aegypti; Darwin port facility; interception response

Introduction

In early January 2011, the dengue mosquito Aedes aegypti was detected at the Darwin port facility of Perkins Shipping at Frances Bay in Darwin, Northern Territory (NT) of Australia. The NT is regarded as one of the very few areas of the tropics free of any of the potential vectors of dengue.¹ The adult collection was made in a Biogents (BG) sentinel trap², which is usually baited with cylinder dispensed carbon dioxide (CO₂), but was unbaited on this occasion due to unavailability. The trap was run continuously from 29/12/10 and collected on 04/01/11. The Medical Entomology (ME) section of the Centre for Disease Control, NT Department of Health (DoH), in cooperation with the Australian Quarantine Inspection Service (AQIS), engages in programs for the inspection, surveillance and treatment of risk cargo and port environs to prevent the establishment of exotic mosquitoes in the NT.³

Detection

The mosquito collection from a routine AQIS BG trap was received by ME on the day of collection (04/01/11). ME entomologists confirmed the identification of 1 male and 2 female Ae. aegypti.

The marine vessel implicated in the introduction (CEC Accord Voyage CA009) berthed in Darwin on 26/12/2010 and was cleared by AQIS on 29/12/10. The manifest of the vessel indicated there were 18 transport containers, with 16 of these being tank container types, which have previously been shown capable of collecting water in a section of their access hatch⁴. However none of the tank containers from the vessel voyage of 26 December were found to be capable of pooling water in their access hatches. The remaining 2 transport containers were open topped, with 1 housing oversized tyres. These tyres had already been unloaded onsite at Perkins and cleared by AQIS.

Control response

Adult Mosquito Control

On the evening of 06/01/11, ME conducted a vehicle mounted Ultra Low Volume (ULV) fogging application of bioresmethrin insecticide to eliminate any further exotic adult mosquitoes that may have been present. The application of the fog was conducted along a similar route to previous interception responses³,⁴ and included the Perkins Shipping international berthing area, the general Perkins Shipping yards, and the adjacent area to the south at the Frances Bay Marine premises (Figure).

Larval Survey and Control

On the following day (07/01/11), 2 AQIS officers and 5 ME personnel conducted a larval survey and receptacle treatment of the entire Perkins Shipping yards. Alpha-cypermethrin insecticide (a pyrethroid) was applied by hand held pressure sprayers to all actual and possible water holding receptacles. AQIS personnel conducted larval surveys of the adjoining premises of Frances Bay Marine on 10/01/11, while ME personnel conducted an insecticide treatment of this site on the following day.
Enhanced adult mosquito surveillance

AQIS responded to this exotic detection by increasing the level of passive surveillance in the port area. The details are as follows. Three cylinder dispensed CO$_2$ baited BG adult mosquito traps were deployed on the day of detection. The BG traps were run continuously for 1 week. Catch bags were collected and reset after every 24 hrs. After the initial week, CO$_2$ baited BG traps were still run continuously, but catch bags were collected every 5 days. This trapping schedule was maintained for 3 weeks. A CO$_2$ baited encephalitis virus surveillance (EVS) trap was set weekly in the Perkins area as per routine, with trapping conducted overnight from mid-afternoon to approximately 10:00 am the next morning. Four extra ovitraps (special traps used to collect eggs laid by Aedes mosquitoes) were set on the 28/01/10 and serviced weekly for 4 weeks by AQIS.

Results

No Ae. aegypti adults or larvae were recovered from any of the heightened surveillance activities in response to the initial detection. There were a number of breeding sites recorded from the larval survey, including vehicle tyres, skip bins holding water, and a septic tank that required mosquito proofing. Perkins undertook to rectify the breeding sites as a source reduction measure.

Discussion

A number of detections of exotic mosquito breeding in cargo arriving at Darwin port have been made over the past 18 months. Tank containers used to transport fuel have been identified as high risk cargo and are now routinely inspected to ensure they are not capable of holding water in the area near their access hatches.$^4$ Other risk cargo include tyres and machinery capable of holding water.$^5$

A recent detection of 3 x 3rd instar Aedes albopictus larvae was made on the 29/12/10. These larvae were detected in a cable drum, a break bulk consignment from the same
The current detection of *Ae. aegypti* had emerged from the cable drum breeding site after treatment.

In comparison, no adult exotic mosquitoes have been detected in routine CO2 baited EVS traps at Darwin port areas since the current routine monitoring program recommenced in 29/09/99. It is therefore recommended that routine CO2 baited BG traps be incorporated into quarantine surveillance around risk ports in Australia to detect exotic *Aedes* mosquitoes. These should be run continuously for at least 5 days each week to ensure increased trapping efficiency.

The current enhanced surveillance and elimination procedures following these importation events significantly reduce the likelihood of a viable population of the dengue vectors entering through the port areas and establishing in Darwin, or spreading to other NT towns.

**Acknowledgements**

Participants of this recent survey and control operation, including operational support include:

- AQIS personnel - Mary Finlay-Doney, Chris Ganambar and Louise Baume; Medical Entomology personnel – Peter Whelan, Nina Kurucz, William Pettit, Jane Carter, Alex Roberts, and Eva Molenar.
- Perkins personnel are thanked for their ongoing assistance. The Department of Health and Ageing are thanked for their funding support to NT Department of Health for these elimination responses.
